

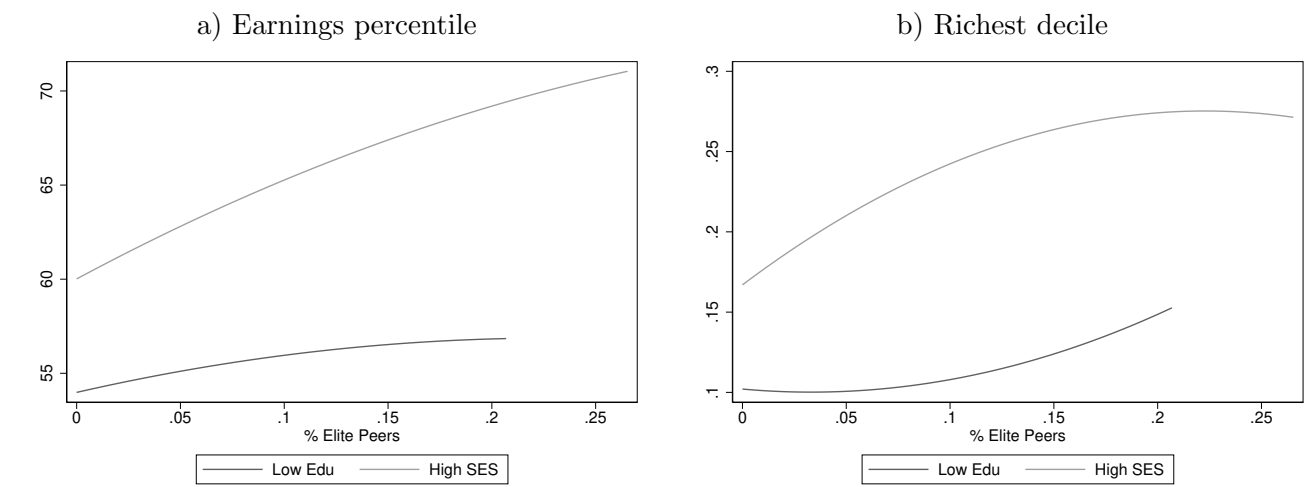

Figure A9: Marginal effect of exposure to elite social networks on student earnings age 30-32 implied from quadratic specification

Notes: This graph plots the marginal effect of an increase in P_{-ics} on earnings as a function of P_{-ics} as implied by estimates of β_{11} and β_{12} in equation (??) but with the dependent variable changed to the earnings percentile (Panel A) and an indicator for earning in the richest decile (Panel B). The marginal effect in the low SES (high SES) sample is plotted as a dark (lighter) line. The estimates of these coefficients are reported in Column (5) of [Table A10](#).
